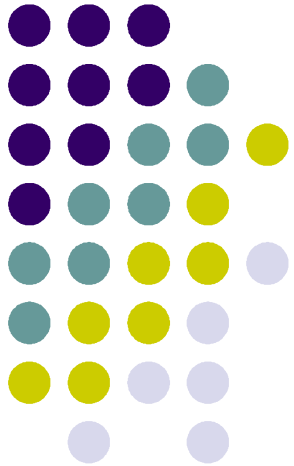
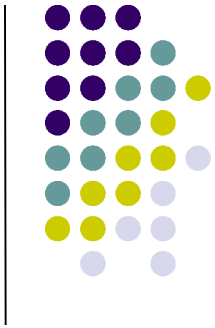
What You Need to Know for Project Three

Dave Eckhardt
Steve Muckle



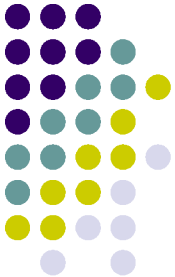
Synchronization



Project 2 due tonight

- Please check “make html_doc” and “make print” are ok
- File arranging: mygroup/p2/Makefile should exist
  - not mygroup/p2/p2/Makefile
  - not mygroup/p2/our_project_2/Makefile
  - not mygroup/p2/p2_tar_file
- Please use the late-day request page to request late days (if necessary) – once for each late day
- Please don't mail us files

Synchronization



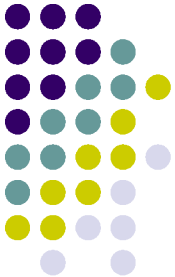
Exam coordinates

- Voting in progress... please vote if you haven't!

Project 3 Checkpoint 1 demo

- Wednesday, March 2nd: class in Wean 52xx cluster
- Attendance is ***mandatory*** (*nobody* has a conflict!)
  - We expect you even if you're not at the checkpoint
  - Regardless of the reason

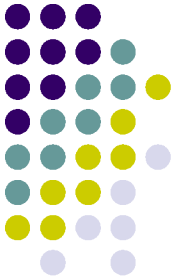
Synchronization



- Reminder: Book report
  - Please don't complain end-of-semester due date!

- Thinking about the future
  - Summer internship with SCS Facilities?
  - Fall: 15-412, OS Practicum
  - Spring: 15-610, Engineering Complex Large-Scale Computer Systems

Overview



Introduction to the Kernel Project

Mundane Details in x86

- registers, paging, the life of a memory access, context switching, system calls, kernel stacks

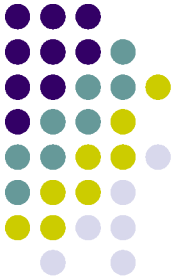
Loading Executables

Style Recommendations (or pleas)

Attack Strategy

A Quick Debug Story

Introduction to the Kernel Project



P3:P2 :: P2:P1!

P2

- Stack, registers, stack, race conditions, stack

P3

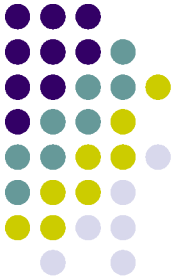
- Stack, registers, page tables, scheduling, races...

You will “become one with” program execution

P1: living without common assumptions

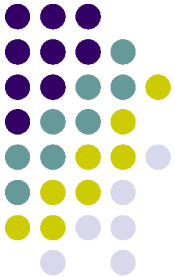
P3: providing those assumptions to users

The P3 Experience



- Goals/challenges
  - More understanding
    - Of OS
    - Practice with synthesizing design requirements
  - More code
    - More planning
    - More organization
  - More quality!
    - Robust
  - ***More debugging!***

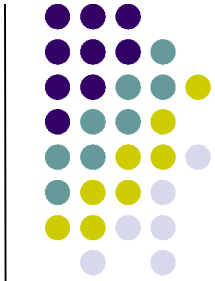
Introduction to the Kernel Project: Kernel Features



Your kernels will feature:

- preemptive multitasking
- multiple virtual address spaces
- a “small” selection of useful system calls
- robustness (hopefully)

Introduction to the Kernel Project: Preemptive Multitasking

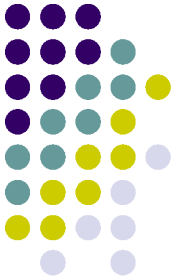


Preemptive multitasking is forcing multiple user processes to share the CPU

You will use the timer interrupt to do this

Reuse your timer code from P1 if possible

Introduction to the Kernel Project: Preemptive Multitasking



Simple round-robin scheduling will suffice

- Some system calls will modify the sequence
- Think about them before committing to a design

Context switching is tricky but cool

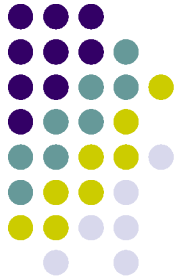
As in P2, creating a new task/thread is hard

- Especially given memory sharing

As in P2, exiting is tricky too

- At least one “How can I do that???” question

Introduction to the Kernel Project: Multiple Virtual Address Spaces



The x86 architecture supports paging

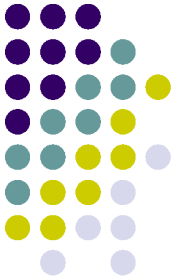
You will use this to provide a virtual address space for each user task

Each user task will be isolated from others

Paging will also protect the kernel from users

Segmentation will not be used for protection

Introduction to the Kernel Project: System Calls



You used them in P2

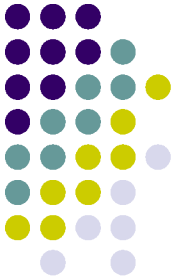
Now you get to implement them

Examples include fork(), exec(), thread_fork

There are easier ones like gettid()

- The core cluster – must work solidly
  - fork(), exec()
  - vanish(), wait()

Mundane Details in x86



We looked at some of these for P1

Now it is time to get the rest of the story

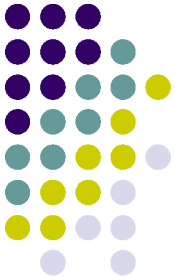
How do we control processor features?

What does an x86 page table look like?

What route does a memory access take?

How do you switch from one process to another?

Mundane Details in x86: Registers



General purpose regs (not interesting)

Segment registers (somewhat interesting)

- %cs, %ss, %ds, %es, %fs, %gs

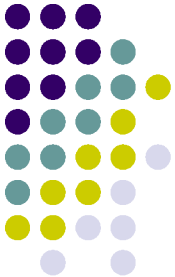
%eip (a little interesting)

EFLAGS (interesting)

Control Registers (very interesting)

- %cr0, %cr1, %cr2, %cr3, %cr4
- esp0 field in the hardware “task segment”

Mundane Details in x86: General Purpose Registers



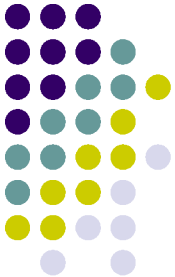
The most boring kind of register

%eax, %ebx, %ecx, %edx, %edi, %esi, %ebp, %esp

%eax, %ebp, and %esp are exceptions, they are slightly interesting

- %eax is used for return values
- %esp is the stack pointer
- %ebp is the base pointer

Mundane Details in x86: Segment Selector Registers



Slightly more interesting

%cs specifies the segment used to access code (also specifies privilege level)

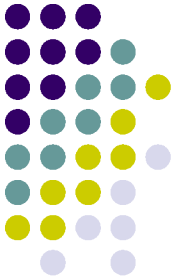
%ss specifies the segment used for stack related operations (pushl, popl, etc)

%ds, %es, %fs, %gs specify segments used to access regular data

Mind these during context switches!!!

If something specific breaks, check these

Mundane Details in x86: The Instruction Pointer (%eip)



It’s interesting

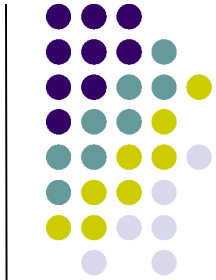
Cannot be read from or written to directly

- (branch, call, return)

Controls which instructions get executed

‘nuff said.

Mundane Details in x86: The EFLAGS Register



It's interesting

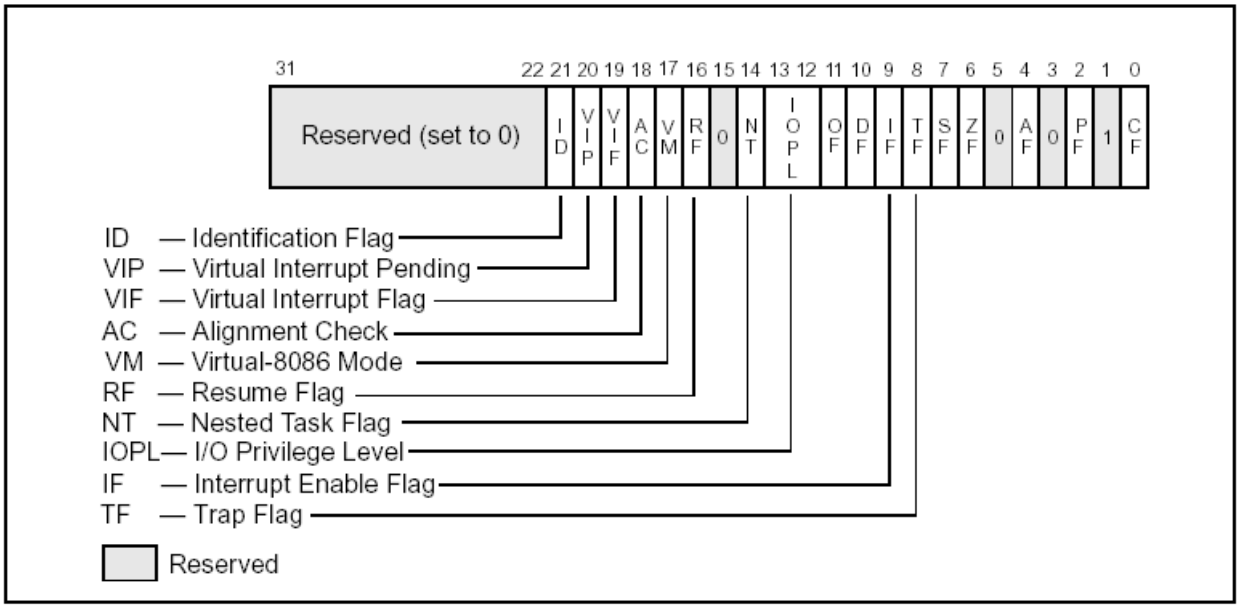


Figure 2-3. System Flags in the EFLAGS Register

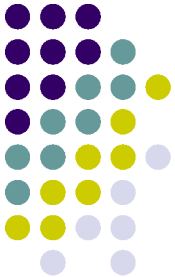
Flag city, including interrupt-enable, arithmetic flags

- You want "alignment check" off

Mundane Details in x86: Control Registers



Very interesting!

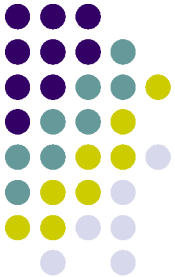
An assortment of important flags and values

%cr0 contains powerful system flags that control things like paging, protected mode

%cr1 is reserved (now that's really interesting)

%cr2 contains the address that caused the last page fault

Mundane Details in x86: Control Registers, cont.



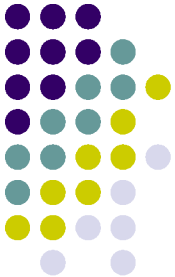
%cr3 contains the address of the current page directory, as well as a couple paging related flags

%cr4 contains… more flags (not as interesting though)

- Protected mode virtual interrupts?
- Virtual-8086 mode extensions?
- Most of these are not usefully modified...

...but you should make an inventory.

Mundane Details in x86: Registers



How do you write to a special register?

Most of them: **`movl`** instruction

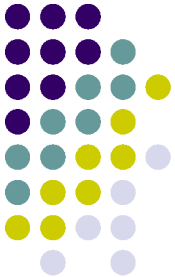
Some (like %cr's) you need PL0 to access

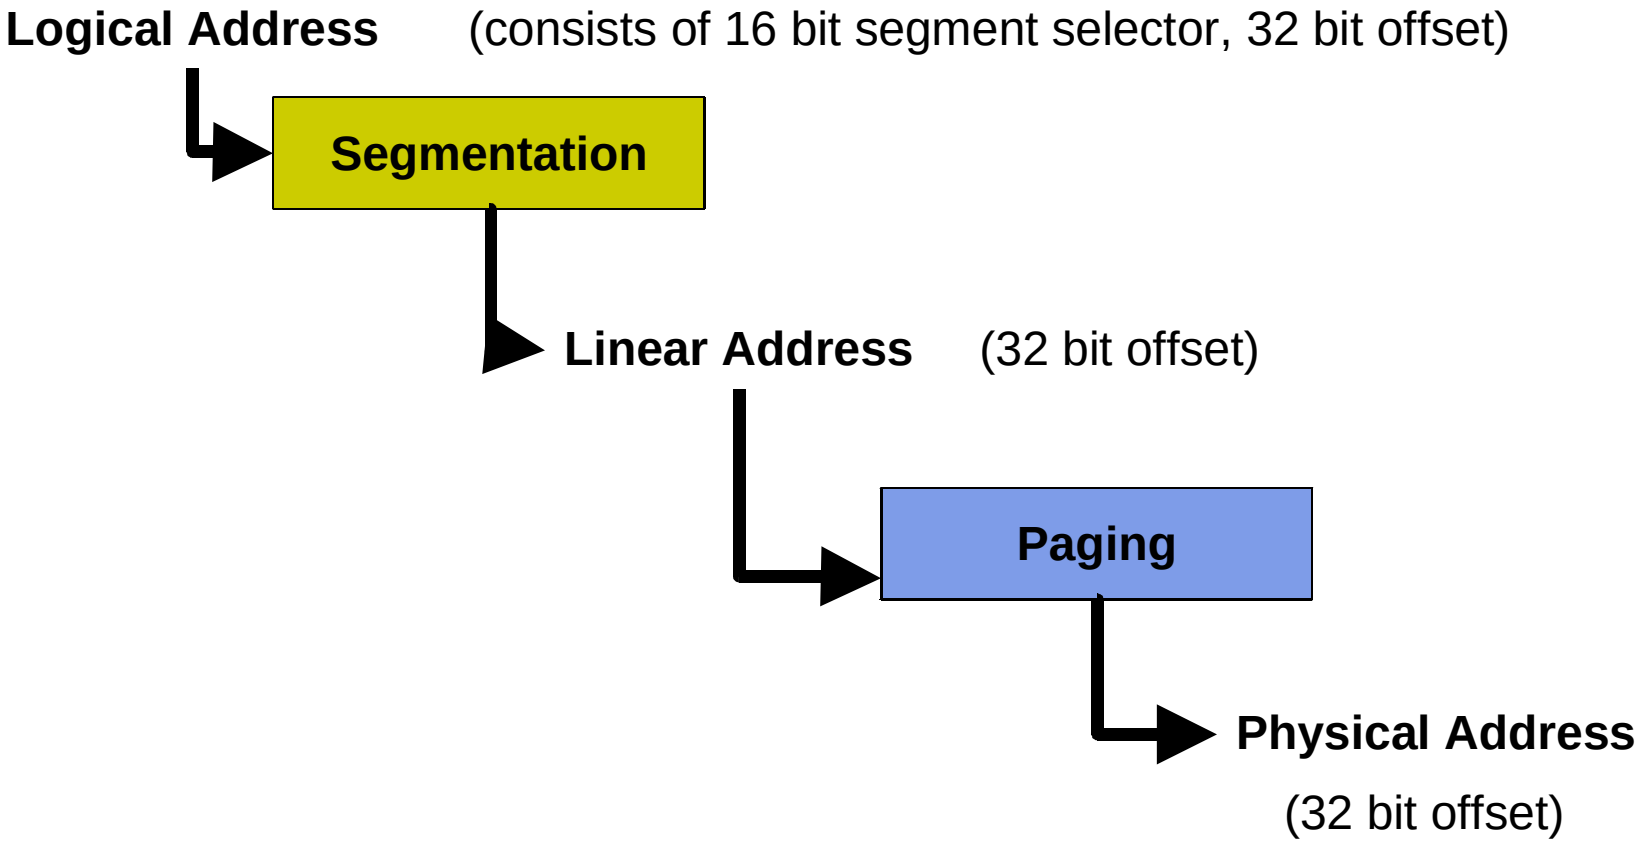
We provide assembly wrappers for some

- Maybe we should skip some!
- Think about each before using.

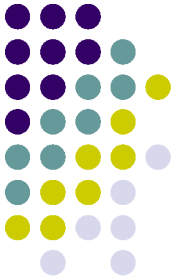
EFLAGS is a little different, but you may not be writing directly to it anyway

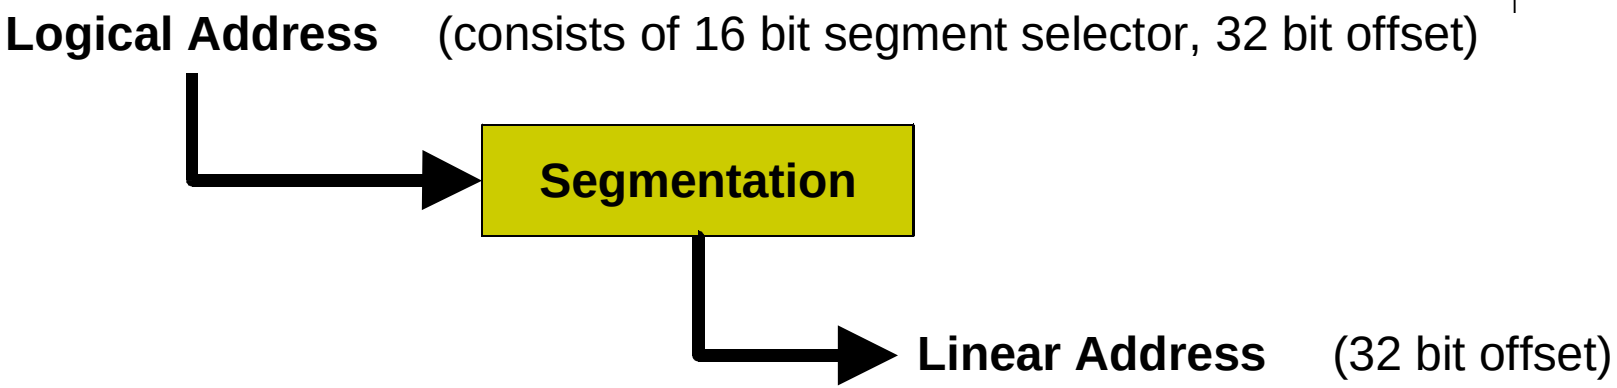
Mundane Details in x86: The Life of a Memory Access





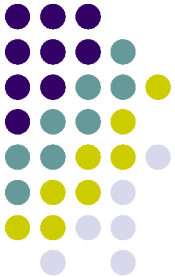
Mundane Details in x86: The Life of a Memory Access





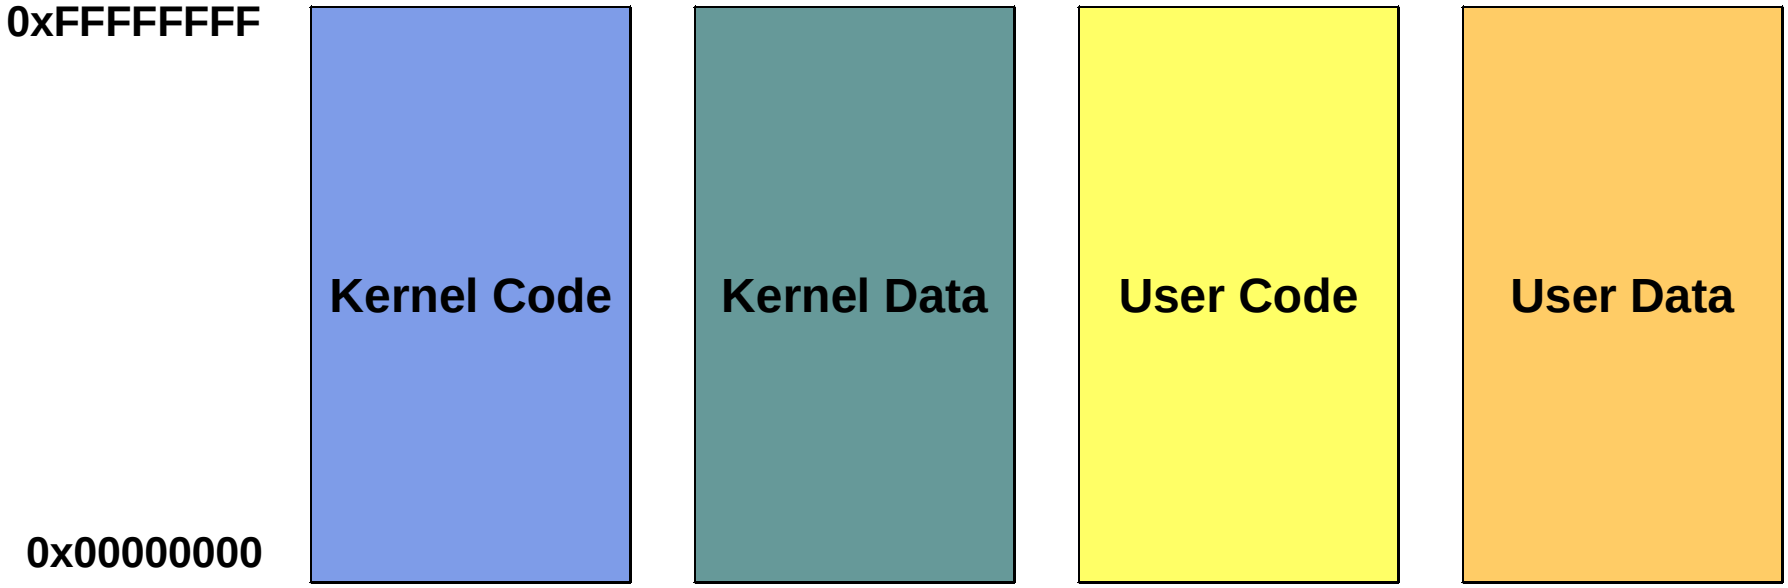
- The 16 bit segment selector comes from a segment register (%CS & %SS implied)
- The 32 bit offset is added to the base address of the segment
- That gives us a 32 bit offset into the virtual address space

Mundane Details in x86: Segmentation

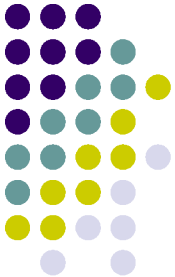


Segments need not be backed by physical memory and can overlap

Segments defined for these projects:



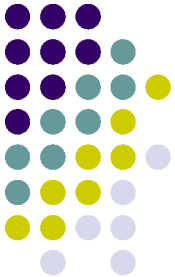
Mundane Details in x86: Segmentation

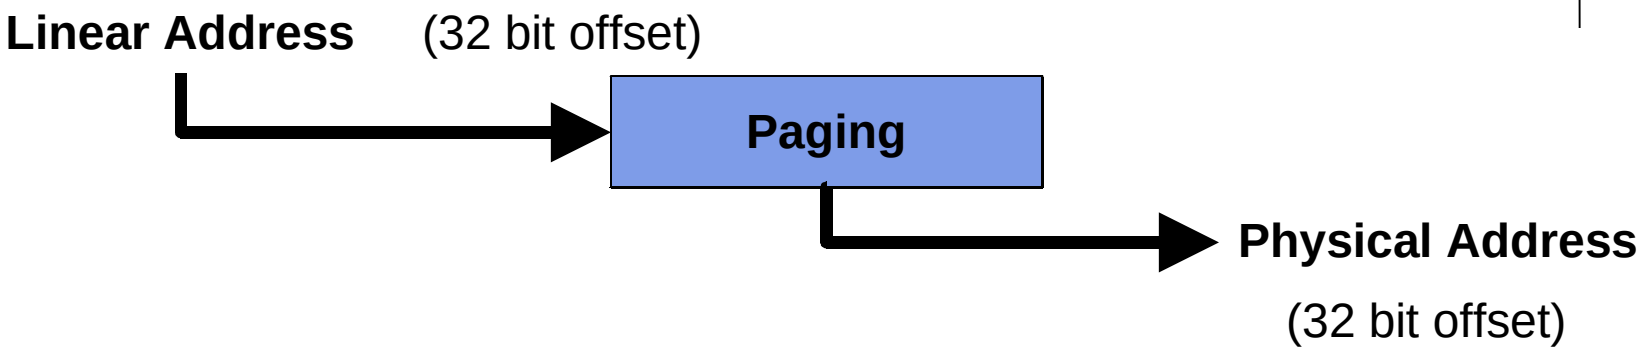


For Project 3 we are abusing segmentation

- All segments “look the same”
- Each linear address is just the “low-order 32 bits” of the logical address
- Confusing, but simplifies life for you
- See 15-410 segmentation guide on web site

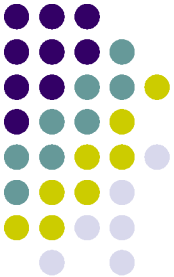
Mundane Details in x86: The Life of a Memory Access

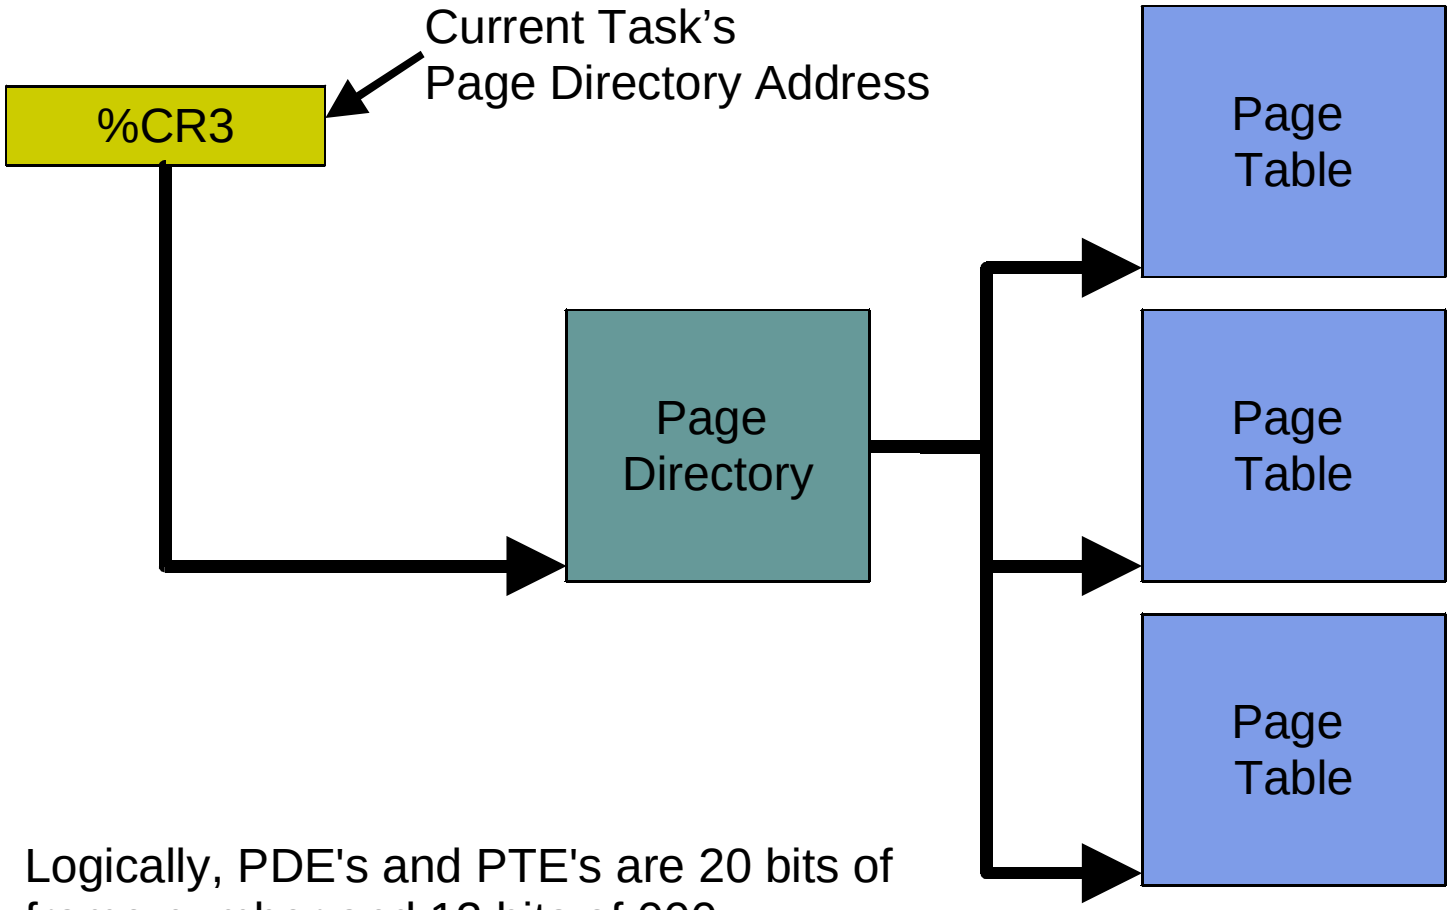




- Top 10 bits index into page directory, point us to a page table
- The next 10 bits index into page table, point us to a page
- The last 12 bits are an offset into that page

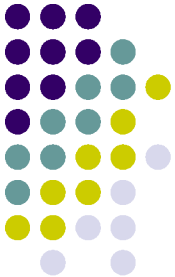
Mundane Details in x86: Page Directories and Tables





Logically, PDE's and PTE's are 20 bits of frame number and 12 bits of 000.

Mundane Details in x86: Page Directory



The page directory is
- 4k in size

Contains
- pointers
- to page tables

Entries may be
- invalid (see "P" bit)

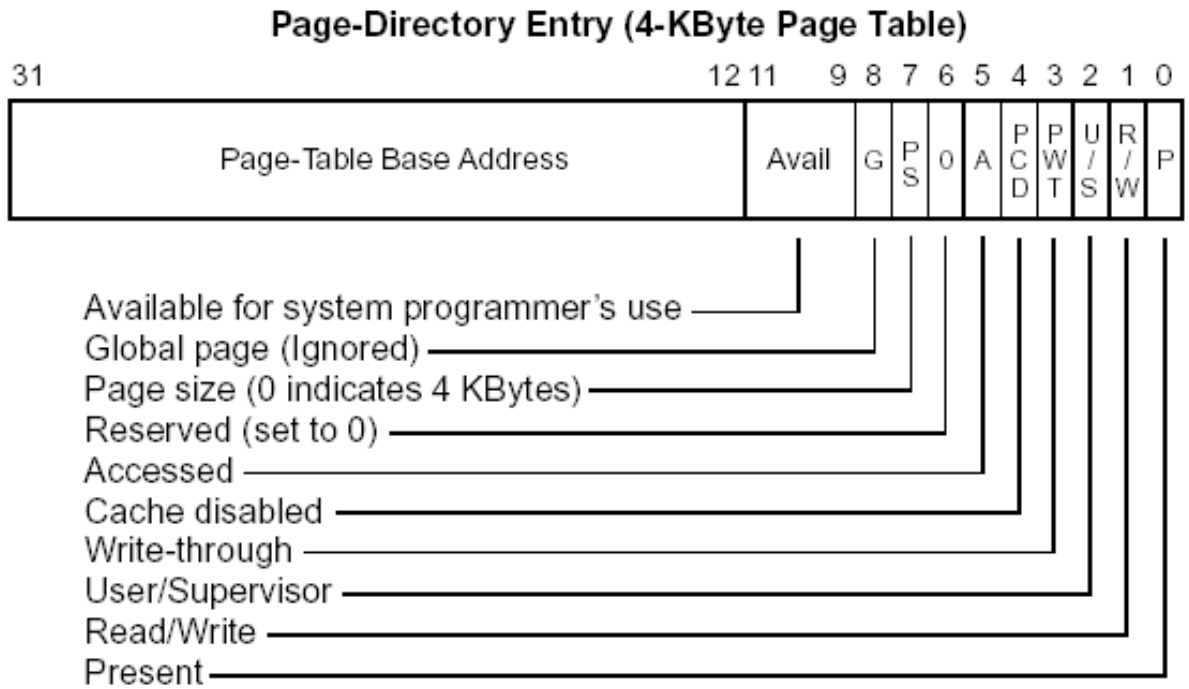


Figure from page 87 of intel-sys.pdf
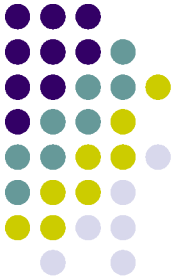
This a jumping-off point!

Mundane Details in x86: Page Table



The page table is also 4k in size

Contains pointers to pages

"P" bit again

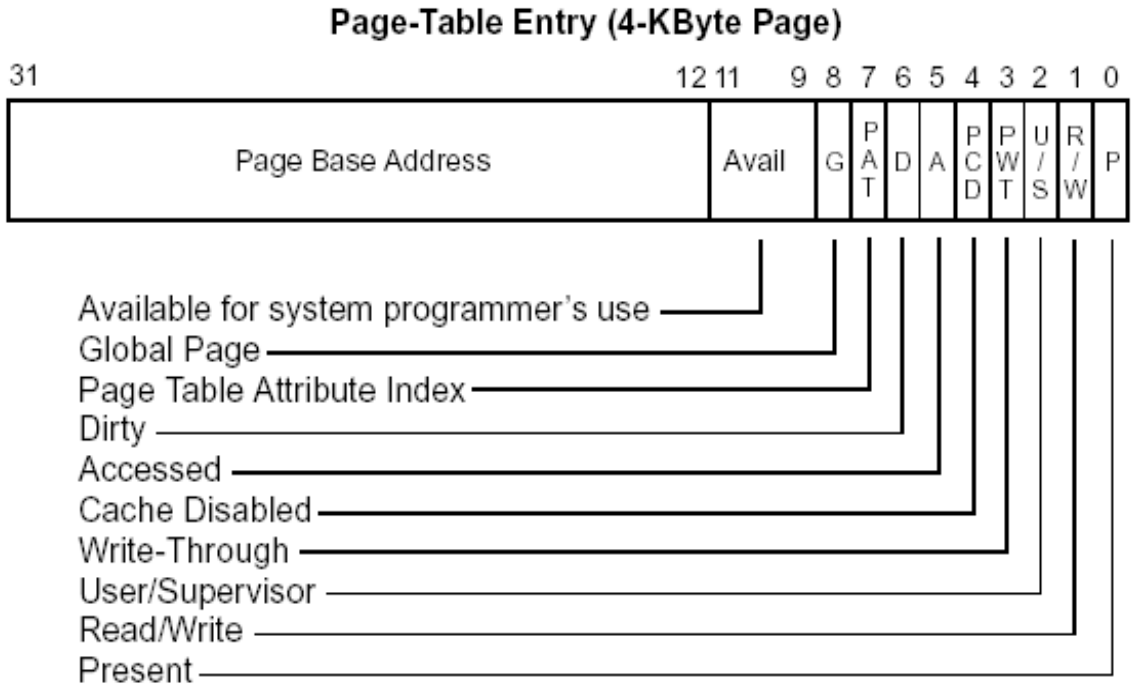


Figure from page 87 of intel-sys.pdf
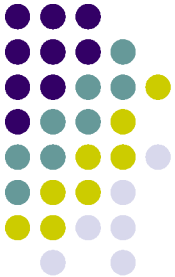
This a jumping-off point!

Mundane Details in x86: The Life of a Memory Access



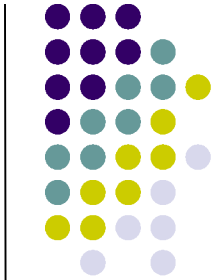
Whoa there, Slick… What if the page directory entry isn't there?

What happens if the page table entry isn't there?

It's called a page fault, it's an exception, and it lives in IDT entry 13

You will have to write a handler for this exception and do something intelligent

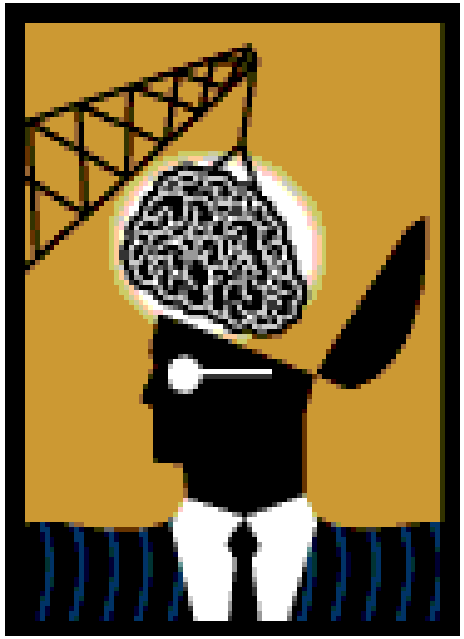
Mundane Details in x86: Context Switching



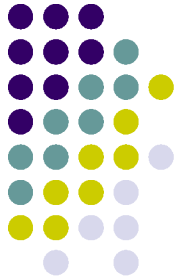
We all know that
processes take turns
running on the CPU

This means they have to
be stopped and started
over and over

How?



Mundane Details in x86: Context Switching



The x86 provides a hardware “task” abstraction

- This makes context switching “easy”

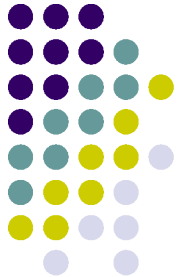
But...

- Often faster to manage processes in software
- We can also tailor our process abstraction to our particular needs
- Our OS is more portable if it doesn't rely on one processor's notion of “task”

Protected mode requires one hardware task

- Already set up by 410 boot code

Mundane Details in x86: Context Switching



Context switching is a very delicate procedure

Great care must be taken so that when the thread is restarted, it does not know it ever stopped

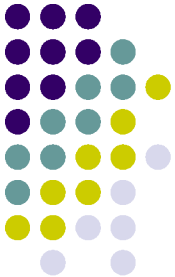
"User" registers must be exactly the same (%cr3 is the key non-user register)

Its stack must be exactly the same

Its page directory must be in place

Please carefully heed the handout warnings!

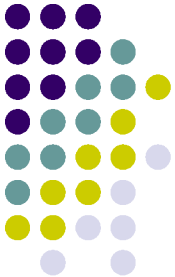
Mundane Details in x86: Context Switching



Hints on context switching:

- Use the stack, it is a convenient place to store things
- If you do all your switching in one routine, you have eliminated one thing you have to save (%eip)
- New threads will require some special care
  - Try to confine new-thread code; don't infect your beautiful pure context-switcher

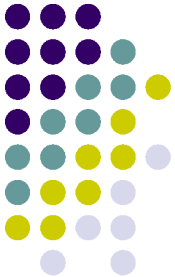
Mundane Details in x86: System Calls



System calls use “software interrupts”

- Which are not actually interrupts!
  - They are immune to disable_interrupts()
    - Which *defers*, not disables, anyway!

Mundane Details in x86: System Calls



System calls use “software interrupts”

- Which are not actually interrupts
  - They are immune to disable_interrupts()
    - Which *defers*, not disables, anyway

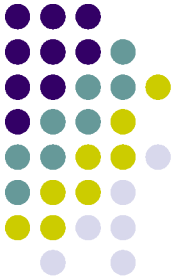
Install handlers just as you did for the timer, keyboard

Calling convention specified in handout

- Matches P2

If you are rusty on the IDT refer back to P1

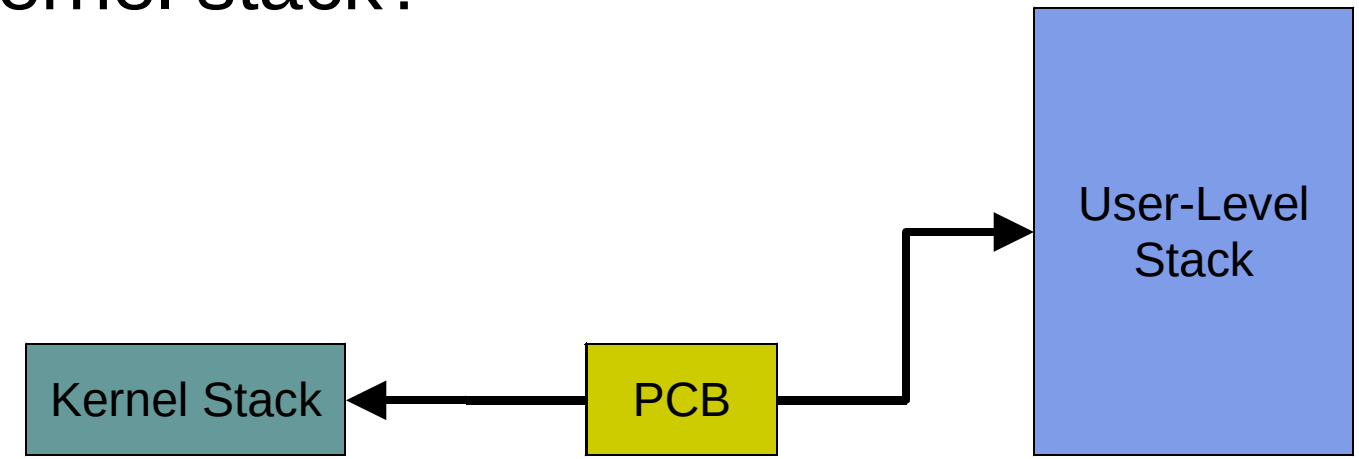
Mundane Details in x86: Kernel Stacks



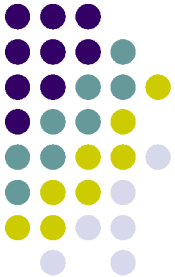
User processes have a separate stack for their kernel activities

Located in kernel space

How does the stack pointer get switched to the kernel stack?



Mundane Details in x86: Kernel Stacks



When the CPU switches from user mode to kernel mode the stack pointer is changed

The new (kernel) stack pointer to use is stored in the configuration of the CPU hardware task

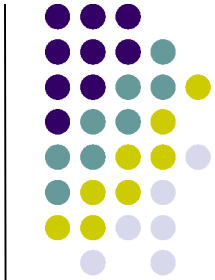
- Remember: we use only one “x86 task”

We provide a function to change this value set_esp0(void* ptr)

Used during next user ⇒ kernel transition

- So set_esp0() “does nothing” (until later)

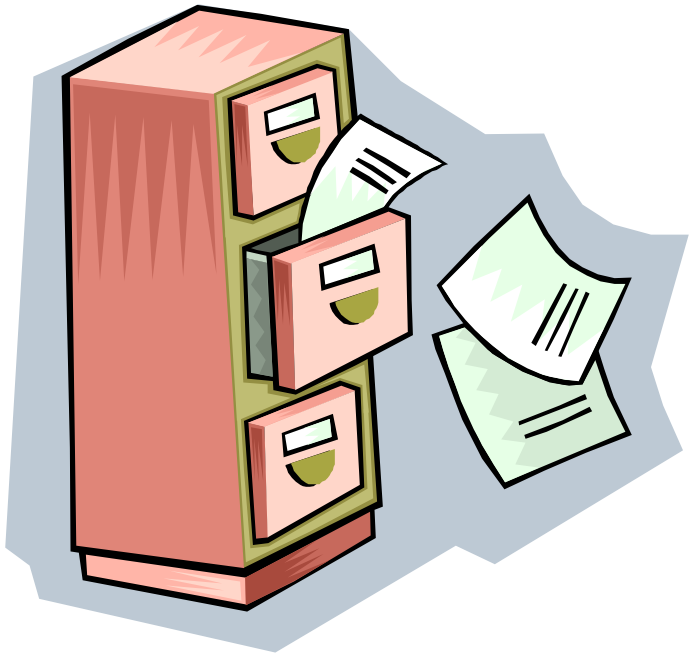
Loading Executables



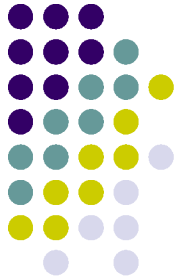
Same approach as P2

"RAM disk" file system

But you must write a loader



Loading Executables: The Loader



RAM-disk bytes are part of the kernel data area

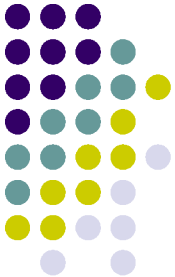
You need to load them into the task's address space

Code, rodata, data, bss, stack – all up to you!

Executables will be in "simple ELF" format

References to resources are in the handout

Encapsulation!!!!!



You will re-implement chunks of your kernel

It will be painful if code is holographic

Don't “use a linked list of threads”

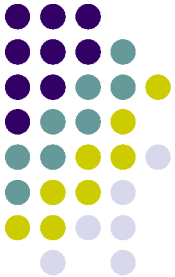
Do define a process-list interface

- find(), append(), first(), ...

You may need to add a method...

- ...which changes the implementation entirely...
- But most existing interface uses (calls) will be ok

Machine State Summary



256 MB RAM, keyboard, console, timer

IDT

CPU state

- General-purpose registers
- Segment registers
- EFLAGS, cr0...cr4, esp0

We set up for you

- Hardware task
- GDT (global descriptor table) – 4 segments

Attack Strategy

There is an attack strategy in the handout

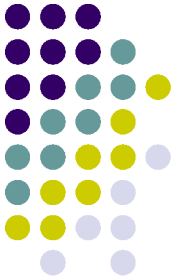
It represents where we think you should be in particular weeks

You WILL have to turn in checkpoints

Excellent data indicate...

Missing one checkpoint is dangerous...don't miss two!

Attack Strategy



Please read the handout a couple times over the next few days

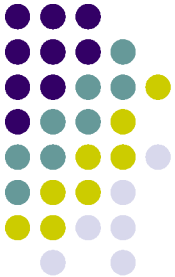
Create doxygen-only files

- scheduler.c, process.c, ...
- Document major functions
- Document key data structures
- A very iterative process

Suggestion: doxygen tentative responsibilities

- For a good time, estimate #lines, #days

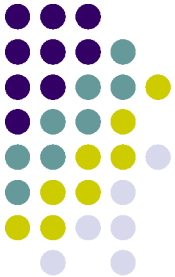
Partnership



Make an explicit partnership plan

- How often you'll meet, for how long
  - Regular, fixed meetings are vital!
- Information flow
  - When will you read each other's code?
- Meeting agenda suggestions
  - Last time's open issues
  - New issues
  - Who will do what by next meeting?

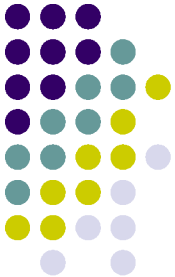
Grading Approach



These numbers are not final!

Weight	*Section*
5	**Kernel builds as directed**
45	**Shell loads, runs test programs**
10	**Concurrency**
10	**Style/structure**
10	**Basic tests**
15	**Non-basic tests**
5	**Thread tests (not using your P2)**

“Hurdle” Model



We will release a test suite

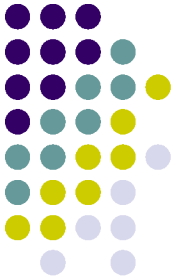
- ~15 “basic” tests
- ~15 “solidity” tests
- ~2 “stability” tests

Successful completion of Project 3 requires

- ~80% of each section of test suite
- Acceptable preemptibility

You will self-test your P3 when you turn it in

“Hurdle” Model



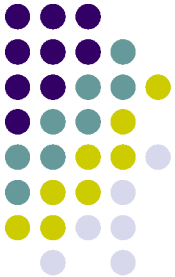
Leap the P3 hurdle?

- Work on Project 4
  - ~2 weeks after P3
  - ~5% of course grade
- A modification/extension of your kernel
  - Goal: “interesting”, more than “hard”

Thwarted?

- Extra time for P3 (~1 week)
- 0% will be assigned for P4 grade

Warning!



To continue to P4, kernel must be complete

- We will publish criteria
- Seemingly “trivial” things on the checklist cost 20% of grade!

P3extra is *not optional* if kernel isn't complete

- We won't assign a P4 grade, so p3extra is the only option

This is serious

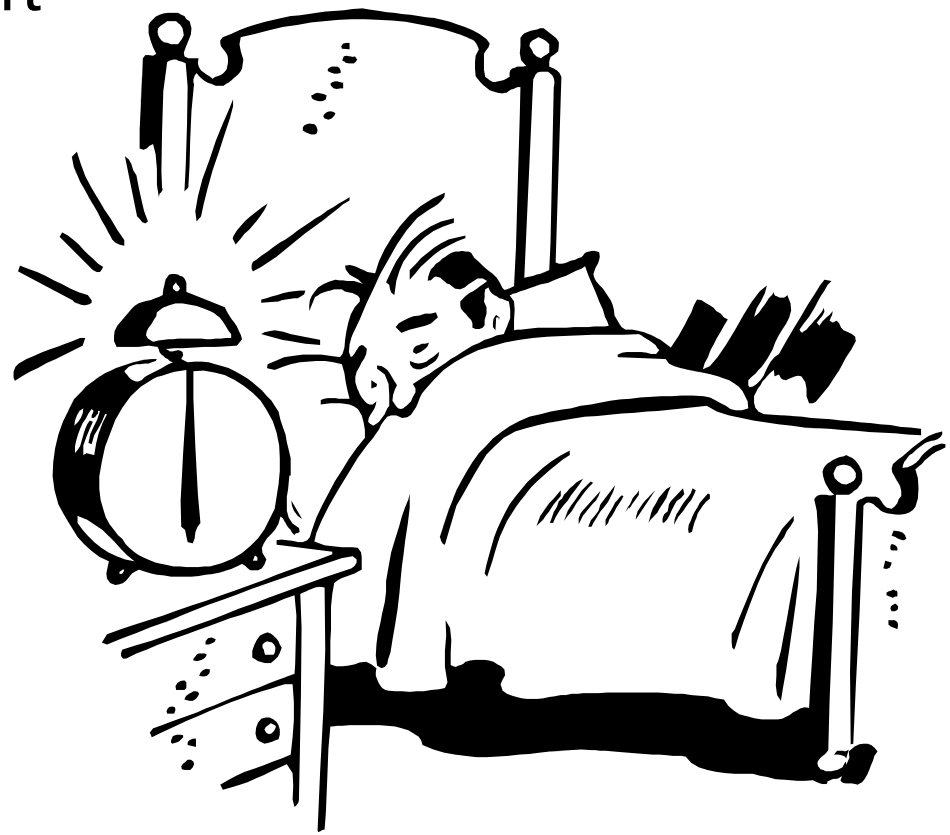
- Please be serious about it

A Quick Debug Story

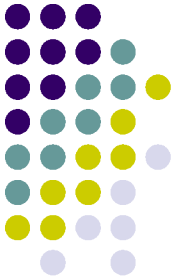
Ha! You'll have to have been to lecture to hear this story.

A Quick Debug Story

The moral is, please start early.



Our Hopes for You



Project 3 can be a transformative experience

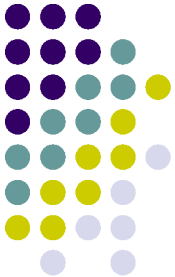
- You may become a different programmer
  - Techniques, attitudes

Employers care about this experience

Alumni care about this experience

#include <end_of_412_concern_stories>

Exhortation

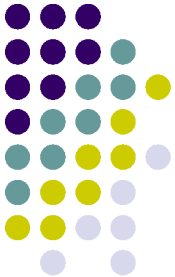


Please read the project handout today!

You need to plan how to get to Checkpoint 1

- Simple loader
- Dummy VM
  - *please* write (encapsulated) bad code!!
- Getting from kernel mode to user mode
- Getting from user mode to kernel mode
- Lots of faults
  - Solving them will require “story telling”

Encouragement



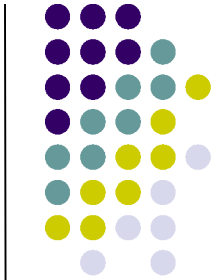
This can be done

Stay on track

- Make all checkpoints
- Don't ignore the plan of attack
- Don't postpone merges

Spring 2009

- 2 groups dropped, one group split
- All other groups turned in working kernels
- Let's do it again!



Good Luck on Project 3!
