

CMSC 412 Fall 2004

Security

Announcements

- Reading
 - Chapter 19 (today)
 - Chapter 20 (next time)
- Final exam review
 - Second half of class Wednesday
- Finals week office hours
 - Tuesday (12/14) 2-4pm
 - Wednesday (12/15) 2-4pm

Who do you trust?

- Do I trust a login prompt?
- Do I trust the OS that I got from the vendor?
- Do I trust the system staff?
 - should I encrypt all my files?
- Networking
 - do you trust the network provider?
 - do you trust the phone company?
- How do you bootstrap security?
 - need one “out of band” transfer to get going

The Security Problem

- Security must consider external environment of the system, and protect it from:
 - unauthorized access
 - modification or destruction of data
 - denial of service
- Easier to protect against accidental than malicious misuse.

Authentication

- When an operation is performed, the computer must know which policy to check to authorize it
- Policies are based on user ids. Thus: we need a way to associate a process with a user id.
 - Bootstrap for the “initial process” and then give the same user id to all sub processes

Passwords

- User identity most often established through *passwords*, can be considered a special case of either keys or capabilities.
- Passwords must be kept secret.
 - Frequent change of passwords.
 - Use of “non-guessable” passwords.
 - Log all invalid access attempts.

Example (UNIX passwords)

- use a function that is hard to invert
 - “easy” to compute $f(x)$ given x
 - hard to compute x given $f(x)$
 - the function used is a variation on the DES algorithm
 - changes selected items in the transformation matrix to prevent hardware attacks
 - store only $f(x)$ in the filesystem
- to login
 - user supplies a password x'
 - compute $f(x')$ and compare to $f(x)$
- salt
 - add an extra two characters to x so that the same x will produce different values on different machines
- dictionary attack
 - if it's easy to compute $f(x)$
 - can “guess” many passwords and try them out

Other authenticators

- Biometric data
- One-time passwords
 - Password function; checked with challenge/response
 - On-time pad; password, once used, is discarded. Pad obtained from trusted source

Computer Authentication

- How does a user know what computer they are using?
- Need to have *mutual authentication*
 - computer presents some information that only it could contain
 - example: Windows <ctrl>-<alt>- to login
 - user software can't trap that information
 - assumes that the kernel itself is secure
- telephone example
 - never give banking/credit card info over the phone unless you placed the phone call
 - i.e. you use the telco namespace for authentication

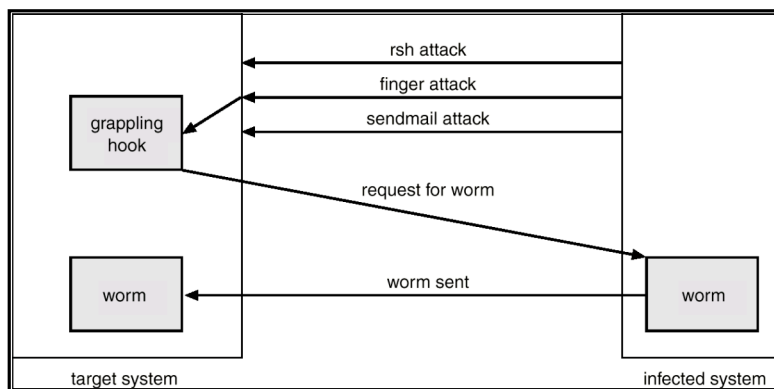

Program Threats

- Trojan Horse
 - Code segment that misuses its environment.
 - Exploits mechanisms for allowing programs written by users to be executed by other users.
- Trap Door
 - Specific user identifier or password that circumvents normal security procedures.
 - Could be included in a compiler.
- Stack and Buffer Overflow

System Attacks

- Worms
 - Standalone program
 - Self-propagates
- Internet worm
 - Exploited UNIX networking features (remote access) and bugs in *finger* and *sendmail* programs.
 - Grappling hook program uploaded main worm program.

The Morris Internet Worm

System Attacks

- Viruses - fragment of code embedded in a legitimate program. (Popularly speaking, worm and virus tend to be used synonymously.)
 - Located in acquired program; set in motion when the program is run.
 - Possible to write system independent viruses
 - MS Word virus uses macros to call into the OS
- Denial of Service
 - Overload the targeted computer preventing it from doing any useful work.

Threat Monitoring

- Check for suspicious patterns of activity - i.e., several incorrect password attempts may signal password guessing.
- Audit log - records the time, user, and type of all accesses to an object; useful for recovery from a violation and developing better security measures.
- Scan the system periodically for security holes; done when the computer is relatively unused.

Threat Monitoring (Cont.)

- Check for:
 - Short or easy-to-guess passwords
 - Unauthorized set-uid programs
 - Unauthorized programs in system directories
 - Unexpected long-running processes
 - Improper directory protections
 - Improper protections on system data files
 - Dangerous entries in the program search path (Trojan horse)
 - Changes to system programs: monitor checksum values

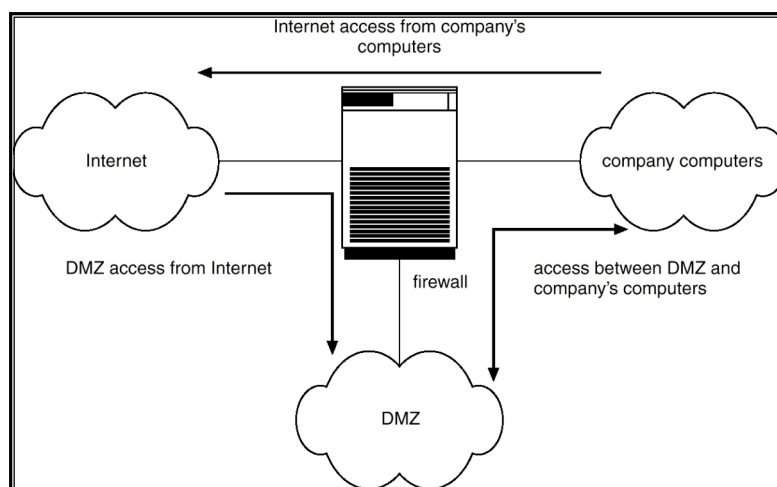

Tripwire

- Compute a set of expectations about system
 - Hash of file contents
 - Dates on files
- Store database of values
 - On read-only media
 - Offline
- Periodically
 - Compare database to current system
 - Report any differences

Firewall

- A firewall is placed between trusted and untrusted hosts.
- The firewall limits network access between these two security domains.

Network Security Through Domain Separation Via Firewall

Intrusion Detection

- Detect attempts to intrude into computer systems.
 - Anomaly detection: know what “normal” behavior is and look for anomalies
 - Signature detection: know what “bad” behavior is and look for that
- Behavior is determined by auditing and logging
 - Process log messages
 - Network traffic
 - System call monitoring

Encryption

- Encrypt clear text into cipher text.
- Properties of good encryption technique:
 - Relatively simple for authorized users to encrypt and decrypt data.
 - Encryption scheme depends not on the secrecy of the algorithm but on a parameter of the algorithm called the encryption key.
 - Extremely difficult for an intruder to determine the encryption key.

Encryption: protecting info from being read

- Given a message m
 - use a key k , and function E_k to compute $E_k(m)$
 - store or send only $E_k(m)$
 - use a second key k' and function $D_{k'}$, such that
 - $D_{k'}(E_k(m)) = m$
 - E and D need not be kept a secret

Encryption Techniques

- For $D_{k'}(E_k(m)) = m$:
- If $k=k'$ it's called **symmetric key encryption**
 - need to keep k secret
 - example Data Encryption Standard (DES)
- if $k \neq k'$, it's called **public key encryption**
 - By keeping k' secret, anyone can send a private message using k
 - still need a way to authenticate k or k' for a user
 - example RSA

Data Encryption Standard

- *Data Encryption Standard (DES)*
substitutes characters and rearranges their order on the basis of an encryption key provided to authorized users via a secure mechanism.
Scheme only as secure as the mechanism.
- New standard: AES Rijndahl.
 - Developed through public competition

One Time Pad

- Key Idea: randomness in key
- Create a random string as long as the message
 - each party has the pad
 - xor each bit of the message with the a bit of the key
- Almost impossible to break
- Some practical problems
 - need to ensure key is not captured
 - a one bit drop will corrupt the rest of the message

Public Key Encryption

- Public-key encryption based on each user having two keys:
 - public key - published key used to encrypt data.
 - private key - key known only to individual user used to decrypt data.
- Must be an encryption scheme that can be made public without making it easy to decrypt the messages.
 - Efficient algorithm for testing whether or not a number is prime.
 - No efficient algorithm is known for finding the prime factors of a number.

RSA

- RSA (Rivest-Shamir-Adelman) first public key system.
 - algorithm for computing public/private key pairs
 - based on problems involved in factoring large primes
 - for an n bit message P , $C = (P^e \bmod n)$, and $P = (C^d \bmod n)$
- Other PE schemes: El-Gamal, Knapsack, DSA, ...

Message Authentication Schemes

- Use a digital signature to ensure authenticity
 - Does not require signed document to be encrypted
- Given a message m
 - use a key k , and function S_k to compute $S_k(m)$
 - send $(m, S_k(m))$
 - use a second key k' and function $V_{k'}$, such that
 - $V_{k'}(m, S_k(m)) = \text{true or false}$
 - S and V need not be kept a secret
- Most encryption schemes support MAC

Secure Communications - SSL

- SSL - Secure Socket Layer
- Cryptographic protocol that limits two computers to only exchange messages with each other.
- Used between web servers and browsers for secure communication (credit card numbers)
- The server is verified with a **certificate**.
- Communication between each computers uses symmetric key cryptography.

SSL handshake

- Client requests connection with server
 - Provides a random number n_c
- Server responds to client, providing
 - Certificate
 - Contains public key, other attributes
 - Signed by Certificate Authority (Verisign)
 - Random number n_s
- Client verifies the signature on the certificate

SSL handshake

- Client generates pre-master secret, sends that to server encrypted with server's public key
- Server decrypts message
- Both client and server now know n_s , n_c , and pms , and calculate $f(n_c, n_s, pms)$: the shared secret
- Shared secret used to encrypt future communications

Computer Security Classifications

- U.S. Department of Defense four divisions of computer security: **A**, **B**, **C**, and **D**.
- **D** - Minimal security.
- **C** - Provides discretionary protection through auditing. Divided into **C1** and **C2**. **C1** identifies cooperating users with the same level of protection. **C2** allows user-level access control.
- **B** - All the properties of **C**, however each object may have unique sensitivity labels. Divided into **B1**, **B2**, and **B3**.
- **A** - Uses formal design and verification techniques to ensure security.
